Data Analysis with Python

Exploratory Data Analysis

Welcome!

In this section, we will explore several methods to see if certain characteristics or features can be used to predict car price.

Table of content

Import Data from Module

Analyzing Individual Feature Patterns using Visualization

Descriptive Statistical Analysis

Basics of Grouping

Correlation and Causation

ANOVA

Estimated Time Needed: 30 min

What are the main characteristics which have the most impact on the car price?

1. Import Data from Module 2

Setup

Import libraries

```
[1]: import pandas as pd  
import numpy as np
```

load data and store in dataframe df:

This dataset was hosted on IBM Cloud object click [HERE](https://s3-api.us-gio.objectstorage.softlayer.net/cf-courses-data/CognitiveClass/DA0101EN/automobileEDA.csv) for free storage

```
[2]: path='https://s3-api.us-gio.objectstorage.softlayer.net/cf-courses-data/CognitiveClass/  
→DA0101EN/automobileEDA.csv'  
df = pd.read_csv(path)  
df.head()
```

```
[2]: symboling  normalized-losses      make aspiration num-of-doors \  
0         3         122  alfa-romero      std         two  
1         3         122  alfa-romero      std         two  
2         1         122  alfa-romero      std         two  
3         2         164      audi      std         four
```

4	2	164	audi	std	four	
---	---	-----	------	-----	------	--

	body-style	drive-wheels	engine-location	wheel-base	length	...
0	convertible	rwd	front	88.6	0.811148	...
1	convertible	rwd	front	88.6	0.811148	...
2	hatchback	rwd	front	94.5	0.822681	...
3	sedan	fwd	front	99.8	0.848630	...
4	sedan	4wd	front	99.4	0.848630	...

	compression-ratio	horsepower	peak-rpm	city-mpg	highway-mpg	price
0	9.0	111.0	5000.0	21	27	13495.0
1	9.0	111.0	5000.0	21	27	16500.0
2	9.0	154.0	5000.0	19	26	16500.0
3	10.0	102.0	5500.0	24	30	13950.0

2	12.368421	Medium	0	1
3	9.791667	Medium	0	1
4	13.055556	Medium	0	1

[5 rows x 29 columns]

2. Analyzing Individual Feature Patterns using Visualization

To install seaborn we use the pip which is the python package manager.

```
[3]: %%capture
      ! pip install seaborn
```

Import visualization packages “Matplotlib” and “Seaborn”, don’t forget about “%matplotlib inline” to plot in a Jupyter notebook.

```
[4]: import matplotlib.pyplot as plt
      import seaborn as sns
      %matplotlib inline
```

How to choose the right visualization method?

When visualizing individual variables, it is important to first understand what type of variable you are dealing with. This will help us find the right visualization method for that variable.

```
[5]: # list the data types for each column
      print(df.dtypes)
```

symboling	int64
normalized-losses	int64
make	object
aspiration	object

num-of-doors	object
body-style	object
drive-wheels	object
engine-location	object
wheel-base	float64
length	float64

Question #1:

What is the data type of the column “peak-rpm”?

Double-click here for the solution.

for example, we can calculate the correlation between variables of type “int64” or “float64” using the method “corr”:

[6]: df.corr()

```
[6]:      symboling  normalized-losses  wheel-base  length \
symboling      1.000000      0.466264 -0.535987 -0.365404
normalized-losses 0.466264      1.000000 -0.056661 0.019424

diesel	-1.000000
gas	1.000000

The diagonal elements are always one; we will study correlation more precisely Pearson correlation in-depth at the end of the notebook.

Question #2:

Find the correlation between the following columns: bore, stroke, compression-ratio, and

horsepower.

Hint: if you would like to select those columns use the following syntax: `df[['bore','stroke','compression-ratio','horsepower']]`

```
[ ]: # Write your code below and press Shift+Enter to execute
```

Double-click here for the solution.

Continuous numerical variables:

Continuous numerical variables are variables that may contain any value within some range. Continuous numerical variables can have the type “int64” or “float64”. A great way to visualize these variables is by using scatterplots with fitted lines.

In order to start understanding the (linear) relationship between an individual variable and the price. We can do this by using “regplot”, which plots the scatterplot plus the fitted regression line for the data.

Let’s see several examples of different linear relationships:

Positive linear relationship

Let’s find the scatterplot of “engine-size” and “price”

```
[7]: # Engine size as potential predictor variable of price
sns.regplot(x="engine-size", y="price", data=df)
plt.ylim(0,)
```

/home/jupyterlab/conda/envs/python/lib/python3.6/site-packages/scipy/stats/stats.py:1713: FutureWarning: Using a non-tuple sequence for multidimensional indexing is deprecated; use `arr[tuple(seq)]` instead of `arr[seq]`. In the future this will be interpreted as an array index, `arr[np.array(seq)]`, which will result either in an error or a different result.

```
return np.add.reduce(sorted[indexer] * weights, axis=axis) / sumval
```

```
[7]: (0, 55967.158254529415)
```

As the engine-size goes up, the price goes up: this indicates a positive direct correlation between these two variables. Engine size seems like a pretty good predictor of price since the regression line is almost a perfect diagonal line.

We can examine the correlation between 'engine-size' and 'price' and see it's approximately 0.87

```
[8]: df[["engine-size", "price"]].corr()
```

```
[8]:      engine-size  price
engine-size    1.000000  0.872335
price          0.872335  1.000000
```

Highway mpg is a potential predictor variable of price

```
[9]: sns.regplot(x="highway-mpg", y="price", data=df)
```

```
[9]: <matplotlib.axes._subplots.AxesSubplot at 0x7fea342c8be0>
```

As the highway-mpg goes up, the price goes down: this indicates an inverse/negative relationship between these two variables. Highway mpg could potentially be a predictor of price.

We can examine the correlation between 'highway-mpg' and 'price' and see it's approximately -0.704

```
[10]: df[['highway-mpg', 'price']].corr()
```

```
[10]:      highway-mpg    price
highway-mpg    1.000000 -0.704692
price          -0.704692  1.000000
```

Weak Linear Relationship

Let's see if "Peak-rpm" as a predictor variable of "price".

```
[11]: sns.regplot(x="peak-rpm", y="price", data=df)
```

```
[11]: <matplotlib.axes._subplots.AxesSubplot at 0x7fea34233860>
```

Peak rpm does not seem like a good predictor of the price at all since the regression line is close to horizontal. Also, the data points are very scattered and far from the fitted line, showing lots of variability. Therefore it's not a reliable variable.

We can examine the correlation between 'peak-rpm' and 'price' and see it's approximately -0.101616

```
[12]: df[['peak-rpm', 'price']].corr()
```

```
[12]:      peak-rpm    price
peak-rpm  1.000000 -0.101616
price    -0.101616  1.000000
```

Question 3 a):

Find the correlation between x="stroke", y="price".

Hint: if you would like to select those columns use the following syntax: df[["stroke", "price"]]

```
[ ]: # Write your code below and press Shift+Enter to execute
```

Double-click here for the solution.

Question 3 b):

Given the correlation results between "price" and "stroke" do you expect a linear relationship? Verify your results using the function "regplot()".

```
[13]: # Write your code below and press Shift+Enter to execute
sns.regplot(x="stroke", y="price", data=df)
```

```
[13]: <matplotlib.axes._subplots.AxesSubplot at 0x7fea34207828>
```

[Double-click here for the solution.](#)

Categorical variables

These are variables that describe a 'characteristic' of a data unit, and are selected from a small group of categories. The categorical variables can have the type "object" or "int64". A good way to visualize categorical variables is by using boxplots.

Let's look at the relationship between "body-style" and "price".

```
[14]: sns.boxplot(x="body-style", y="price", data=df)
```

```
[14]: <matplotlib.axes._subplots.AxesSubplot at 0x7fea34116e80>
```

We see that the distributions of price between the different body-style categories have a significant overlap, and so body-style would not be a good predictor of price. Let's examine engine "engine-location" and "price":

```
[15]: sns.boxplot(x="engine-location", y="price", data=df)
```

```
[15]: <matplotlib.axes._subplots.AxesSubplot at 0x7fea34167e10>
```

Here we see that the distribution of price between these two engine-location categories, front and rear, are distinct enough to take engine-location as a potential good predictor of price.

Let's examine "drive-wheels" and "price".

```
[16]: # drive-wheels  
sns.boxplot(x="drive-wheels", y="price", data=df)
```

```
[16]: <matplotlib.axes._subplots.AxesSubplot at 0x7fea2fbd33c8>
```

Here we see that the distribution of price between the different drive-wheels categories differs; as such drive-wheels could potentially be a predictor of price.

3. Descriptive Statistical Analysis

Let's first take a look at the variables by utilizing a description method.

The describe function automatically computes basic statistics for all continuous variables. Any NaN values are automatically skipped in these statistics.

This will show:

the count of that variable

the mean

the standard deviation (std)

the minimum value

the IQR (Interquartile Range: 25%, 50% and 75%)

the maximum value

We can apply the method "describe" as follows:

[17]: `df.describe()`

```
[17]:      symboling  normalized-losses  wheel-base  length  width \
count  201.000000      201.00000  201.000000  201.000000  201.000000
mean     0.840796      122.00000   98.797015   0.837102   0.915126
std     1.254802      31.99625    6.066366   0.059213   0.029187
min    -2.000000      65.00000   86.600000   0.678039   0.837500
25%     0.000000     101.00000   94.500000   0.801538   0.890278
50%     1.000000     122.00000   97.000000   0.832292   0.909722
75%     2.000000     137.00000  102.400000   0.881788   0.925000
```

max	3.000000	256.00000	120.900000	1.000000	1.000000

The default setting of “describe” skips variables of type object. We can apply the method “describe” on the variables of type ‘object’ as follows:

```
[18]: df.describe(include=['object'])
```

```
[18]:
```

	make	aspiration	num-of-doors	body-style	drive-wheels \
count	201	201	201	201	201

freq	115

Value Counts

Value-counts is a good way of understanding how many units of each characteristic/variable we have. We can apply the “value_counts” method on the column ‘drive-wheels’. Don’t forget the method “value_counts” only works on Pandas series, not Pandas Dataframes. As a result, we only include one bracket “df[‘drive-wheels’]” not two brackets “df[[‘drive-wheels’]]”.

```
[19]: df['drive-wheels'].value_counts()
```

```
[19]: fwd    118
      rwd     75
      4wd     8
      Name: drive-wheels, dtype: int64
```

We can convert the series to a Dataframe as follows :

```
[20]: df['drive-wheels'].value_counts().to_frame()
```

```
[20]: drive-wheels
      fwd    118
      rwd     75
      4wd     8
```

Let’s repeat the above steps but save the results to the dataframe “drive_wheels_counts” and rename the column ‘drive-wheels’ to ‘value_counts’.

```
[21]: drive_wheels_counts = df['drive-wheels'].value_counts().to_frame()
      drive_wheels_counts.rename(columns={'drive-wheels': 'value_counts'}, inplace=True)
      drive_wheels_counts
```

```
[21]: value_counts
      fwd    118
      rwd     75
      4wd     8
```

Now let’s rename the index to ‘drive-wheels’:

```
[22]: drive_wheels_counts.index.name = 'drive-wheels'
      drive_wheels_counts
```

```
[22]: value_counts
drive-wheels
      fwd    118
      rwd     75
      4wd     8
```

We can repeat the above process for the variable ‘engine-location’.

```
[23]: # engine-location as variable
      engine_loc_counts = df['engine-location'].value_counts().to_frame()
      engine_loc_counts.rename(columns={'engine-location': 'value_counts'}, inplace=True)
```

```
engine_loc_counts.index.name = 'engine-location'
engine_loc_counts.head(10)
```

```
[23]:          value_counts
engine-location
front          198
rear            3
```

Examining the value counts of the engine location would not be a good predictor variable for the price. This is because we only have three cars with a rear engine and 198 with an engine in the front, this result is skewed. Thus, we are not able to draw any conclusions about the engine location.

4. Basics of Grouping

The “groupby” method groups data by different categories. The data is grouped based on one or several variables and analysis is performed on the individual groups.

For example, let’s group by the variable “drive-wheels”. We see that there are 3 different categories of drive wheels.

```
[24]: df['drive-wheels'].unique()
```

```
[24]: array(['rwd', 'fwd', '4wd'], dtype=object)
```

If we want to know, on average, which type of drive wheel is most valuable, we can group “drive-wheels” and then average them.

We can select the columns ‘drive-wheels’, ‘body-style’ and ‘price’, then assign it to the variable “df_group_one”.

```
[25]: df_group_one = df[['drive-wheels', 'body-style', 'price']]
```

We can then calculate the average price for each of the different categories of data.

```
[26]: # grouping results
df_group_one = df_group_one.groupby(['drive-wheels'], as_index=False).mean()
df_group_one
```

```
[26]: drive-wheels    price
0      4wd  10241.000000
1      fwd   9244.779661
2      rwd  19757.613333
```

From our data, it seems rear-wheel drive vehicles are, on average, the most expensive, while 4-wheel and front-wheel are approximately the same in price.

You can also group with multiple variables. For example, let’s group by both ‘drive-wheels’ and ‘body-style’. This groups the dataframe by the unique combinations ‘drive-wheels’ and ‘body-style’. We can store the results in the variable ‘grouped_test1’.

```
[27]: # grouping results
df_gptest = df[['drive-wheels', 'body-style', 'price']]
grouped_test1 = df_gptest.groupby(['drive-wheels', 'body-style'], as_index=False).mean()
grouped_test1
```

```
[27]: drive-wheels  body-style    price
0      4wd    hatchback  7603.000000
```

1	4wd	sedan	12647.333333
2	4wd	wagon	9095.750000
3	fwd	convertible	11595.000000
4	fwd	hardtop	8249.000000
5	fwd	hatchback	8396.387755
6	fwd	sedan	9811.800000
7	fwd	wagon	9997.333333
8	rwd	convertible	23949.600000
9	rwd	hardtop	24202.714286
10	rwd	hatchback	14337.777778
11	rwd	sedan	21711.833333
12	rwd	wagon	16994.222222

This grouped data is much easier to visualize when it is made into a pivot table. A pivot table is like an Excel spreadsheet, with one variable along the column and another along the row. We can convert the dataframe to a pivot table using the method “pivot” to create a pivot table from the groups.

In this case, we will leave the drive-wheel variable as the rows of the table, and pivot body-style to become the columns of the table:

```
[28]: grouped_pivot = grouped_test1.pivot(index='drive-wheels',columns='body-style')
grouped_pivot
```

```
[28]:
```

	convertible	hardtop	hatchback	sedan
4wd	NaN	NaN	7603.000000	12647.333333
fwd	11595.0	8249.000000	8396.387755	9811.800000
rwd	23949.6	24202.714286	14337.777778	21711.833333

	wagon
4wd	9095.750000
fwd	9997.333333
rwd	16994.222222

Often, we won’t have data for some of the pivot cells. We can fill these missing cells with the value 0, but any other value could potentially be used as well. It should be mentioned that missing data is quite a complex subject and is an entire course on its own.

```
[29]: grouped_pivot = grouped_pivot.fillna(0) #fill missing values with 0
grouped_pivot
```

```
[29]:
```

	convertible	hardtop	hatchback	sedan
4wd	0.0	0.000000	7603.000000	12647.333333
fwd	11595.0	8249.000000	8396.387755	9811.800000
rwd	23949.6	24202.714286	14337.777778	21711.833333

body-style	wagon
drive-wheels	
4wd	9095.750000
fwd	9997.333333
rwd	16994.222222

Question 4:

Use the “groupby” function to find the average “price” of each car based on “body-style” ?

```
[30]: # Write your code below and press Shift+Enter to execute
df_gptest2 = df[['body-style','price']]
grouped_test_bodystyle = df_gptest2.groupby(['body-style'],as_index=False).mean()
grouped_test_bodystyle
```

```
[30]: body-style    price
0 convertible  21890.500000
1   hardtop    22208.500000
2  hatchback   9957.441176
3     sedan   14459.755319
4     wagon   12371.960000
```

Double-click here for the solution.

If you did not import “pyplot” let’s do it again.

```
[31]: import matplotlib.pyplot as plt
%matplotlib inline
```

Variables: Drive Wheels and Body Style vs Price

Let’s use a heat map to visualize the relationship between Body Style vs Price.

```
[32]: #use the grouped results
plt.pcolor(grouped_pivot, cmap='RdBu')
plt.colorbar()
plt.show()
```

The heatmap plots the target variable (price) proportional to colour with respect to the variables 'drive-wheel' and 'body-style' in the vertical and horizontal axis respectively. This allows us to visualize how the price is related to 'drive-wheel' and 'body-style'.

The default labels convey no useful information to us. Let's change that:

```
[33]: fig, ax = plt.subplots()
      im = ax.pcolor(grouped_pivot, cmap='RdBu')

      #label names
      row_labels = grouped_pivot.columns.levels[1]
      col_labels = grouped_pivot.index

      #move ticks and labels to the center
      ax.set_xticks(np.arange(grouped_pivot.shape[1]) + 0.5, minor=False)
      ax.set_yticks(np.arange(grouped_pivot.shape[0]) + 0.5, minor=False)

      #insert labels
      ax.set_xticklabels(row_labels, minor=False)
      ax.set_yticklabels(col_labels, minor=False)

      #rotate label if too long
      plt.xticks(rotation=90)

      fig.colorbar(im)
      plt.show()
```

Visualization is very important in data science, and Python visualization packages provide great freedom. We will go more in-depth in a separate Python Visualizations course.

The main question we want to answer in this module, is “What are the main characteristics which have the most impact on the car price?”.

To get a better measure of the important characteristics, we look at the correlation of these variables with the car price, in other words: how is the car price dependent on this variable?

5. Correlation and Causation

Correlation: a measure of the extent of interdependence between variables.

Causation: the relationship between cause and effect between two variables.

It is important to know the difference between these two and that correlation does not imply causation. Determining correlation is much simpler than determining causation as causation may require independent experimentation.

Pearson Correlation

The Pearson Correlation measures the linear dependence between two variables X and Y.

The resulting coefficient is a value between -1 and 1 inclusive, where:

1: Total positive linear correlation.

0: No linear correlation, the two variables most likely do not affect each other.

-1: Total negative linear correlation.

Pearson Correlation is the default method of the function “corr”. Like before we can calculate the Pearson Correlation of the of the ‘int64’ or ‘float64’ variables.

[34]: `df.corr()`

sometimes we would like to know the significant of the correlation estimate.

P-value:

What is this P-value? The P-value is the probability value that the correlation between these two variables is statistically significant. Normally, we choose a significance level of 0.05, which means that we are 95% confident that the correlation between the variables is significant.

By convention, when the

p-value is < 0.001 : we say there is strong evidence that the correlation is significant.

the p-value is < 0.05 : there is moderate evidence that the correlation is significant.

the p-value is < 0.1 : there is weak evidence that the correlation is significant.

the p-value is > 0.1 : there is no evidence that the correlation is significant.

We can obtain this information using “stats” module in the “scipy” library.

```
[35]: from scipy import stats
```

Wheel-base vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'wheel-base' and 'price'.

```
[36]: pearson_coef, p_value = stats.pearsonr(df['wheel-base'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P =", p_value)
```

The Pearson Correlation Coefficient is 0.5846418222655081 with a P-value of P = 8.076488270732955e-20

Conclusion:

Since the p-value is < 0.001 , the correlation between wheel-base and price is statistically significant, although the linear relationship isn't extremely strong (~0.585)

Horsepower vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'horsepower' and 'price'.

```
[37]: pearson_coef, p_value = stats.pearsonr(df['horsepower'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P =",
      p_value)
```

The Pearson Correlation Coefficient is 0.8095745670036559 with a P-value of P = 6.36905742825998e-48

Conclusion:

Since the p-value is < 0.001 , the correlation between horsepower and price is statistically significant, and the linear relationship is quite strong (~0.809, close to 1)

Length vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'length' and 'price'.

```
[38]: pearson_coef, p_value = stats.pearsonr(df['length'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ", p_value)
```

The Pearson Correlation Coefficient is 0.690628380448364 with a P-value of P = 8.016477466159053e-30

Conclusion:

Since the p-value is < 0.001 , the correlation between length and price is statistically significant, and the linear relationship is moderately strong (~ 0.691).

Width vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'width' and 'price':

```
[39]: pearson_coef, p_value = stats.pearsonr(df['width'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ", p_value)
```

The Pearson Correlation Coefficient is 0.7512653440522674 with a P-value of P = 9.200335510481426e-38

Conclusion: Since the p-value is < 0.001 , the correlation between width and price is statistically significant, and the linear relationship is quite strong (~ 0.751).

0.0.1 Curb-weight vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'curb-weight' and 'price':

```
[40]: pearson_coef, p_value = stats.pearsonr(df['curb-weight'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ", p_value)
```

The Pearson Correlation Coefficient is 0.8344145257702846 with a P-value of P = 2.1895772388936997e-53

Conclusion:

Since the p-value is < 0.001 , the correlation between curb-weight and price is statistically significant, and the linear relationship is quite strong (~ 0.834).

Engine-size vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'engine-size' and 'price':

```
[41]: pearson_coef, p_value = stats.pearsonr(df['engine-size'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ", p_value)
```

The Pearson Correlation Coefficient is 0.8723351674455185 with a P-value of P = 9.265491622197996e-64

Conclusion:

Since the p-value is < 0.001 , the correlation between engine-size and price is statistically significant, and the linear relationship is very strong (~ 0.872).

Bore vs Price

Let's calculate the Pearson Correlation Coefficient and P-value of 'bore' and 'price':

```
[42]: pearson_coef, p_value = stats.pearsonr(df['bore'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ",
      ↪p_value )
```

The Pearson Correlation Coefficient is 0.5431553832626602 with a P-value of P = 8.049189483935364e-17

Conclusion:

Since the p-value is < 0.001 , the correlation between bore and price is statistically significant, but the linear relationship is only moderate (~ 0.521).

We can relate the process for each 'City-mpg' and 'Highway-mpg':

City-mpg vs Price

```
[43]: pearson_coef, p_value = stats.pearsonr(df['city-mpg'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ",
      ↪p_value)
```

The Pearson Correlation Coefficient is -0.6865710067844677 with a P-value of P = 2.3211320655676368e-29

Conclusion:

Since the p-value is < 0.001 , the correlation between city-mpg and price is statistically significant, and the coefficient of ~ -0.687 shows that the relationship is negative and moderately strong.

Highway-mpg vs Price

```
[44]: pearson_coef, p_value = stats.pearsonr(df['highway-mpg'], df['price'])
print("The Pearson Correlation Coefficient is", pearson_coef, " with a P-value of P = ",
      ↪p_value)
```

The Pearson Correlation Coefficient is -0.7046922650589529 with a P-value of P = 1.7495471144476807e-31

Conclusion: Since the p-value is < 0.001 , the correlation between highway-mpg and price is statistically significant, and the coefficient of ~ -0.705 shows that the relationship is negative and moderately strong.

6. ANOVA

ANOVA: Analysis of Variance

The Analysis of Variance (ANOVA) is a statistical method used to test whether there are significant differences between the means of two or more groups. ANOVA returns two parameters:

F-test score: ANOVA assumes the means of all groups are the same, calculates how much the actual means deviate from the assumption, and reports it as the F-test score. A larger score means there is a larger difference between the means.

P-value: P-value tells how statistically significant is our calculated score value.

If our price variable is strongly correlated with the variable we are analyzing, expect ANOVA to return a sizeable F-test score and a small p-value.

Drive Wheels

Since ANOVA analyzes the difference between different groups of the same variable, the groupby function will come in handy. Because the ANOVA algorithm averages the data automatically, we do not need to take the average before hand.

Let's see if different types 'drive-wheels' impact 'price', we group the data.

Let's see if different types 'drive-wheels' impact 'price', we group the data.

```
[45]: grouped_test2=df_gptest[['drive-wheels', 'price']].groupby(['drive-wheels'])
      grouped_test2.head(2)
```

```
[45]: drive-wheels  price
0      rwd  13495.0
1      rwd  16500.0
3      fwd  13950.0
4      4wd  17450.0
5      fwd  15250.0
136     4wd   7603.0
```

```
[46]: df_gptest
```

```
[46]: drive-wheels  body-style  price
0      rwd  convertible  13495.0
1      rwd  convertible  16500.0
2      rwd   hatchback  16500.0
3      fwd     sedan   13950.0
4      4wd     sedan   17450.0
..     ...     ...     ...
196     rwd     sedan   16845.0
197     rwd     sedan   19045.0
198     rwd     sedan   21485.0
199     rwd     sedan   22470.0
200     rwd     sedan   22625.0
```

[201 rows x 3 columns]

We can obtain the values of the method group using the method "get_group".

```
[47]: grouped_test2.get_group('4wd')['price']
```

```
[47]: 4      17450.0
136    7603.0
140    9233.0
141   11259.0
144    8013.0
145   11694.0
150    7898.0
151    8778.0
Name: price, dtype: float64
```

we can use the function 'f_oneway' in the module 'stats' to obtain the F-test score and P-value.

```
[48]: # ANOVA
```

```
f_val, p_val = stats.f_oneway(grouped_test2.get_group('fwd')['price'], grouped_test2.
    ↳get_group('rwd')['price'], grouped_test2.get_group('4wd')['price'])

print( "ANOVA results: F=", f_val, ", P =", p_val)
```

ANOVA results: F= 67.95406500780399 , P = 3.3945443577151245e-23

This is a great result, with a large F test score showing a strong correlation and a P value of almost 0 implying almost certain statistical significance. But does this mean all three tested groups are all this highly correlated?

Separately: fwd and rwd

```
[49]: f_val, p_val = stats.f_oneway(grouped_test2.get_group('fwd')['price'], grouped_test2.
    ↳get_group('rwd')['price'])

print( "ANOVA results: F=", f_val, ", P =", p_val )
```

ANOVA results: F= 130.5533160959111 , P = 2.2355306355677845e-23

Let's examine the other groups

4wd and rwd

```
[50]: f_val, p_val = stats.f_oneway(grouped_test2.get_group('4wd')['price'], grouped_test2.
    ↳get_group('rwd')['price'])

print( "ANOVA results: F=", f_val, ", P =", p_val)
```

ANOVA results: F= 8.580681368924756 , P = 0.004411492211225333

4wd and fwd

```
[51]: f_val, p_val = stats.f_oneway(grouped_test2.get_group('4wd')['price'], grouped_test2.
    ↳get_group('fwd')['price'])

print("ANOVA results: F=", f_val, ", P =", p_val)
```

ANOVA results: F= 0.665465750252303 , P = 0.41620116697845666

Conclusion: Important Variables

We now have a better idea of what our data looks like and which variables are important to take into account when predicting the car price. We have narrowed it down to the following variables:

Continuous numerical variables:

Length

Width

Curb-weight

Engine-size

Horsepower

City-mpg

Highway-mpg

Wheel-base

Bore

Categorical variables:

Drive-wheels

As we now move into building machine learning models to automate our analysis, feeding the model with variables that meaningfully affect our target variable will improve our model's prediction performance.
